What is soil health?

Soil health in agricultural ecosystems is indicated by a living dynamic ecology providing the needs for healthy plants.

The components of these are:

- adequate air/water balance,
- micro and macro-organism activity and
- appropriate nutrient availability.

They are influenced by:

- soil texture and structure,
- mineral levels,
- organic matter cycling,
- topsoil depth and
- freedom from harmful substances.

Dave Forrest 2007

DICTIONARY OF TERMS

BIOTURBATION:

the mixing of soil organic matter into the soil profile by organisms.

BULK DENSITY:

the measure of how tightly packed soil particles are in soil. The higher the bulk density the lower the soil pore space.

CATION EXCHANGE CAPACITY (CEC):

the capacity of soil to hold nutrients for plant use. Specifically, CEC is the amount of negative charges available on clay and humus to hold positively charged ions. Effective cation exchange capacity (ECEC) is reported for acid soils (pH<5). Expressed as centimoles of charge per kilogram of soil (cmolc/kg).

COMPACTION:

compaction occurs when forces compress the soil and pushes air and water out of it so that it becomes dense.

C:N RATIO:

amount of carbon relative to the amount of nitrogen present in organic matter.

BANKS:

Contour bank:

an earth embankment that runs across the slope following the contour of the land, with a shallow channel on the upslope side. It is designed as a barrier to surface water flow.

Graded bank:

similar to a contour bank but designed to have very slight fall along the upslope drain channel. The grade is usually 0.1–0.5%.

Diversion bank:

specially designed bank with drain on the upslope side that diverts excess water from a sensitive area. It is graded but not usually more than 3%.

EXUDATES:

soluble sugars, amino acids and other compounds secreted by roots.

GROUND COVER:

any plant or plant residue that covers the soil surface and protects it from erosion and moisture loss.

HUMUS:

organic matter that is so decomposed that it can no longer be recognised as individual components is known as humus. The highly complex compounds that make up humus are able to resist further decomposition, and therefore accumulate in the soil.

MINERALISATION:

biological process in which organic compounds are chemically converted to other simpler organic compounds or inorganic forms, such as ammonium or phosphate, by soil microorganisms.

MULCH:

any material that is placed on the surface of the soil.

ORGANIC MATTER:

anything that contains carbon compounds that were formed by living organisms. Examples include lawn clippings, leaves, stems, branches, moss, algae, any animal parts, manure, sawdust, insects, earthworms and microbes.

PEDS:

clumps of soil that stay together as one structure when soil is disturbed with minimal force, such as with a shovel.

SOIL ECOLOGY:

the study of interrelations among soil organisms and between organisms and the soil environment.

SOIL FOOD WEB:

the inter-connected community of organisms living all or part of their lives in the soil.

SOIL ORGANIC MATTER:

the total organic matter in the soil. It can be divided into three general pools: living biomass of micro-organisms, fresh and partially decomposed residues (the active fraction) and the well-decomposed and highly stable organic material. Surface litter is generally not included as part of soil organic matter.

SOIL PH:

a measure of the acidity or alkalinity of soil. The scale range is from 0 (most acid) to 14 (most alkaline) with 7 as neutral. Soil pH can be measured in water or calcium chloride (CaCl₂). If pH is measured in water it is .5 to .8 higher than if measured in CaCl₂.

SOIL STRUCTURE:

the spatial assembly of the soil particles of sand/silt/clay and the spaces between them; the size, shape and arrangement of these aggregates.

STEM FLOW:

water running down a tree trunk during heavy rain.

WATER HOLDING CAPACITY:

the amount of water that can be held in soil against the pull of gravity.

INTRODUCTION AND BACKGROUND

INTRODUCTION

The **Northern Rivers Soil Best Management Practice (BMP) Guide – Perennial Horticulture** has been developed by growers for growers. It offers practical guidelines to improve and maintain soil health for better production and environmental outcomes. The Soil BMP is a 'living' document and as such can be edited and updated as we further our understanding of soil processes on our farms.

The BMP Guide supports the **Northern Rivers Soil Health Card – Perennial Horticulture (SHC-PH)**. The SHC-PH provides 10 straightforward visual tests for landholders to assess soil health in the orchard using simple equipment and can be carried out by the farmer in the field. For information on how to obtain the SHC-PH refer to the 'WANT TO KNOW MORE' section of this document.

BACKGROUND

The Alstonville Plateau Landscape soil commenced production some 20 million years ago when Mt Warning ceased erupting. Under the high rainfall conditions the plateau soil weathered and leached and the rainforests, the 'Big Scrub', grew.

When the first European settlers came to the area they saw lush forests – a teeming biomass of vegetation – supported by the underlying red soil. Fertility and productivity in the Big Scrub depended on nutrient cycling. Nutrients were held in the organic matter on the forest floor which was recycled to the soil.

The prized plateau soils, known as Krasnozems or Red Ferrosols, are relatively high in organic matter (18–20 %) in their natural state in rainforests. Nevertheless on clearing, organic matter declines rapidly to less than 7% within a few years and as low as 2 or 3% if the soil is cultivated and left exposed for long periods (Hungerford 1995). Once cleared these soils have diminished nutrient and organic matter levels compared to the original forested condition.

ALSTONVILLE PLATEAU LANDSCAPE SOILS

Krasnozems/Red Ferrosols formed from basalt parent material under conditions of high rainfall. They are red-brown to orange in colour depending on organic matter content, generally a well structured clay but with localised stoniness. The good structure facilitates high water infiltration, good drainage and aeration. They are commonly deep topsoils (2m+) but have poor chemical properties, e.g. low pH, trace elements and other minerals and nutrients.

Chocolate soils formed from basalt parent material under conditions of lower rainfall. Topsoils are shallow (<1m), brown to black in colour with a loamy clay or clay overlying a paler heavy clay. The subsoil is poorly drained. These soils have good mineral content, but with a high magnesium to calcium ratio making soil structure less stable.

Podsollic soils formed from sedimentary deposits of sandstone, mudstone or shale. The topsoils are shallow (75mm), highly erodible grey to brown loam overlying poorly structured yellow to red clay subsoils. They are infertile with low mineral content, low pH, poor structure and low organic matter.

Alluvial soils vary widely in their features depending on parent material. They are usually fertile because they are composed of eroded topsoil from catchment, but physical properties vary from well-drained loams to poorly structured clays.

Excerpted from Soil Landscapes of the Lismore-Ballina 1:100,000 Sheet

STRENGTHS & WEAKNESSES OF ALSTONVILLE PLATEAU LANDSCAPE SOIL

'STRENGTHS'

The greatest asset of the plateau landscape soil is structure. In good condition it has the following characteristics which makes it physically ideal for plant growth:

- loose and friable (A friable soil is well aerated and allows for good root growth.),
- high permeability to both air and water,
- reasonable ability to hold water that can be accessed by plants (plant available water content),
- low soil strength when moist (allows for easy root penetration in the soil).

This good physical structure allows water to infiltrate easily through the soil. It is not prone to water logging except in low lying areas. It also provides a favourable environment for soil biological organisms to flourish.

Nevertheless, if the soil is not protected it is moderately to highly susceptible to erosion depending on slope and rainfall. Also because of the mineralogical nature of the soil (i.e. the soil lacks minerals that allow it to shrink and swell) once it is structurally damaged, by compaction, for example, it is very hard to repair.

The plateau soil is not saline or sodic.

'WEAKNESSES'

The majority of the 'weaknesses' of the plateau soil are as a result of its formation and use under high rainfall conditions. The plateau soil is weathered and leached and consequently has the following characteristics:

- **Low soil pH:** Soil pH affects the availability of nutrients and chemical species to plant roots. The plateau soil is 'naturally', moderately to strongly acid and has the potential to induce:
 - aluminium and manganese toxicity; manganese toxicity, for example, affects the metabolism of plants causing yellowing and death of leaf tissue.
 - calcium, magnesium and molybdenum deficiencies once pH is below 5 (CaCl_2).
 - reduction in phosphorous (P) availability leading to less root growth and less ability for oil accumulation in the kernel.
- **Moderate to low ability to hold nutrients:** the 'mineral' soil, that is the soil without organic matter, humus etc, has a moderate to low cation exchange capacity (CEC), which means it has limited ability to hold nutrients. Low soil pH contributes to a low nutrient holding capacity. The CEC can be improved by the build up of organic matter and humus in the soil.
- **Low exchangeable Calcium (Ca) and Magnesium (Mg):** At pH below 5, Ca and Mg become deficient and plant growth will be limited as a result.

Soil pH will continue to drop particularly under acidifying conditions of high annual rainfall and use of acidifying fertilisers such as ammonium phosphate.

ISSUES FOR SOIL HEALTH IN PERENNIAL HORTICULTURE ORCHARDS

Alstonville Plateau Landscape soils have a variable history of soil erosion and other degradation issues due to prior land management practices. The area's high rainfall along with any current unsustainable farm management practices increases the potential for erosion and nutrient leaching.

THE MAIN ISSUES IN PERENNIAL HORTICULTURE ORCHARDS THAT IMPACT ON SOIL HEALTH AND SUBSEQUENTLY PERENNIAL HORTICULTURE PRODUCTION ARE:

- loss of valuable topsoil and topsoil organic matter due to past and present management practices, i.e. clearing, cultivation and erosion.
- declining soil fertility if topsoil and soil organic matter decline or are lost.
- decreasing soil pH (less than pH 5 (CaCl_2)) and associated toxicities (aluminium toxicity) and deficiencies (lack of calcium and magnesium and reduction in soil microbial activity) from leaching rainfall conditions and use of certain nitrogenous fertilisers. See NSW DPI Agnote:
<http://www.dpi.nsw.gov.au/agriculture/resources/soils/acidity/publications/n-acidify>
- breakdown of soil structure by machinery operations, particularly when the soil is wet, and with high intensity rainfall.
- orchard layout and canopy management, particularly as it impacts on canopy closure and loss of light penetration to the orchard floor which suppresses growth of under tree ground cover.
- 'bare soil' management practices

Many of the past and ongoing issues for soil health can be remedied.

Some things I can change or influence as a farmer are:

- I can assess and monitor the health of my soil by utilising the tools such as the Soil Health Card.
- I can then determine, prioritise and manage the risks to soil health in my orchard.
- I can maximise soil cover and minimise soil erosion in the orchard.
- I can manage my orchard to reduce impacts on the structure of the soil.
- I can improve plant nutrition in my orchard by managing soil conditions (chemical, physical and biological) and use of fertilisers and other soil conditioners.
- I can provide soil conditions in my orchard to encourage and promote beneficial soil organisms.

Considerations for soil health in an established orchard.

(see Appendix 1 for new orchards)

- Carry out Soil Health Card test to assess soil health.
- Take soil samples for laboratory testing.
- Determine the issues that impact on soil health e.g. canopy management, ground cover.
- Develop a long-term soil management plan to address the issues.

BMP 1 – MANAGING SOIL EROSION

SOIL HEALTH CARD TESTS: GROUND COVER, INFILTRATION, SOIL STRUCTURE AND EROSION

WHY IS SOIL EROSION IMPORTANT TO ME AS A FARMER?

The topsoil has the best soil structure, contains most nutrients, and has the highest level of soil biological activity and root density. As such it needs to be protected and conserved for crop productivity. Managing the orchard to prevent erosion will maintain the production value of the orchard and the asset value of the land.

- Topsoil erosion may be incremental with only millimetres being removed in one event but over time the healthiest part of the productive capacity is removed.
- High rainfall events are typical of the region so proactive measures need to be taken.
- Erosion means loss of nuts that are washed off and/or buried in the soil that is eroded. This is a direct cost to the farmer.

Left: Tree roots exposed from soil erosion. Photo: P Woods

HOW DO I MANAGE SOIL EROSION?

1. MANAGE WATER FLOW.

- **Control surface run-on.**
- Divert water away from the orchard/block to reduce run-on.
- Divert water to safe disposal area such as flat open space with 100% ground cover or a body of water.
- On slopes greater than 8% (5 degrees), surface drainage structures e.g.; contour and diversion banks and inter-row drains can help to safely dispose of run-off water to stable waterways by shortening slope lengths these structures can reduce impacts on erosion.

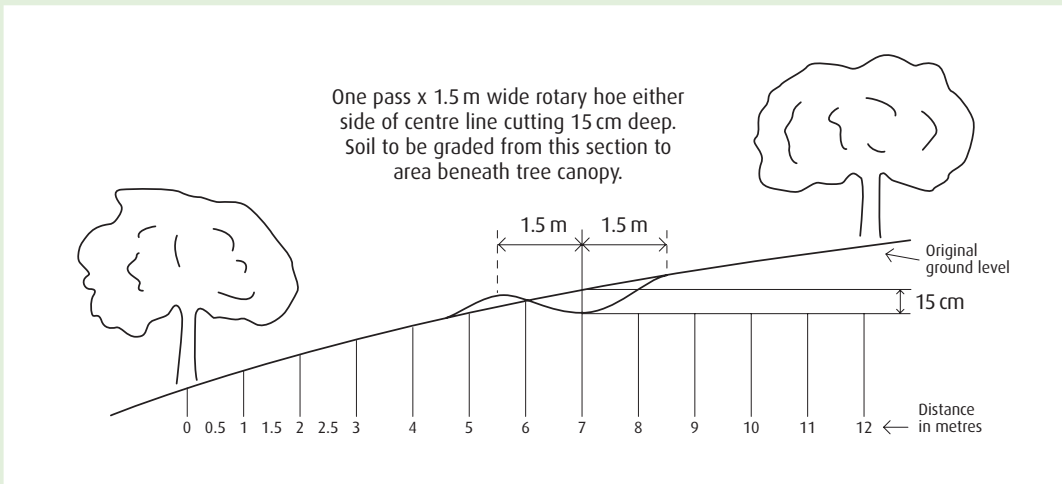

Top left: Rock lined drain diverts surface run-on to a stable gully.
Photo: Lewis-Atkinson
Bottom left: Redirecting run-on via a drain to a stable gully.
Photo: B Walker

- **Control surface run-off.**
- On slopes greater than 8% or 5 degrees, surface drainage structures e.g.; contour and diversion banks and inter-row drains can help to safely dispose of run-off water to stable waterways. By shortening slope lengths these structures can reduce impacts on erosion.
- On slopes greater than 20% or 15 degrees, traditional run-off controls are often not suitable. Consult a qualified soil conservation specialist for advice.
- Establish subtly mounded tree rows and associated grassed drains running directly down slope and in the inter-row area. Designing mounds and drains is best done at establishment of the orchard. (See Appendix 1)
- Ensure inter-row areas are broad and shallow with regular diversion points and have good ground cover.
- Convey run-off across the slope at regular intervals, down-slope via diversion drains discharging into natural water courses or formed grassed waterways.
- Where the potential for extreme erosion is evident consult a qualified soil conservation specialist for advice.
- Do not plant trees in natural drainage ways or immediately next to them and remove those plantings where they exist.
- Do not allow a gutter effect along the edge of the mound as it will be susceptible to erosion.

Cross section between rows running directly downhill.

Drawing adapted from 'Soil Management in Orchards', NSW DPI Agnote DPI-331.

Cross section view: Where side slopes are greater than 10% an extra 2 metres in row spacing should be used in rows with drains. Drawing adapted from 'Soil Management in Orchards', NSW DPI Agnote DPI-331.

2. ESTABLISH, MAINTAIN AND MANAGE GROUND COVER IN THE ORCHARD.

- Maintain living ground covers to provide the best protection against loss of soil because they slow down run-off water after rain, allow water to infiltrate into the soil and lessen evaporation losses.

Types of 'green' ground cover that could be used under trees:

- Sweet smother grass
- Creeping vigna
- Pinto's peanut

Types of 'brown' ground cover or mulch:

- Grass clippings
- Chopped up leaves
- Chipped prunings
- Compost

Left: Pinto's peanut (green) and woodchips (brown) groundcovers

Photo: B Walker

The roots of living ground covers:

- are highly resistant to erosion,
- support soil structure,
- support nutrient cycling,
- support soil biology,
- provide a cushion/buffer against compaction by machinery,
- bind soil particles,
- in combination with mulch provide protection against concentrated 'stem flow' in heavy rain and impacts of rain drops from the canopy which dislodge soil and cause erosion.

(If using herbicide, use knockdown rather than systemic chemicals to leave the root system alive to hold the soil.)

- In drainage lines use grass species with above ground runners or stolons such as Kikuyu or couch and smother grass for shaded areas because they are ground hugging with the ability to spread.
- On easily erodible plateau soil, sloping land and intense rainfall events, 90–100% ground cover is necessary in the tree line. In drainage ways 100% cover is required.
- As the inter-row becomes shaded, plant low-light tolerant ground cover species.

Left: 100% ground cover provides many benefits for soil health.

Photo: B Walker

Maintain mulch covering where living ground covers are not growing.

- Mulch needs to be coarse to resist rapid breakdown and allow good aeration.
- Mulch can also act as a good weed suppressant.
- Use side-throw mowers to throw grass clippings under the trees.

Left: When trees are pruned or removed, the prunings can be chipped to mulch the orchard floor.

Photo: B Walker

4. MANAGE PLANT CANOPY

Light penetration to the orchard floor allows for the growth of ground cover, which protects the soil from erosion and also provides a supportive environment for plant production.

A planned and systematic approach is required for long-term management of the canopy.

Pruning and skirting

Selective limb removal allows the canopy to spread and intercept more light to provide:

- reduced risk of disease,
- better energy balance for the tree,
- better spray penetration and coverage,
- greater crop bearing surface.

Skirting removes lower branches to allow:

- better light penetration in canopy,
- machinery access to allow side throw mowing or slashing,
- minimal herbicide use.

Hedging

- Hedging leaves a clear tunnel of light to the lower branches and ground. It works more effectively for a longer period with wider spaced trees.

Note: Continual hedging may develop a thick, leafy barrier that inhibits light and spray penetration to centre of the tree.

Tree Removal

- For new orchards use wider spacings such as 10m x 5m at establishment. This allows a much longer time before canopy closure.

- In older orchards with narrow spacings, tree removal or renovation (i.e. stumping, selective limb removal) on a planned sequence is necessary.

Left: Every second tree is removed in the row to allow light back to the orchard floor.

Photo: J Luethi

5. BE AWARE OF CURRENT ENVIRONMENTAL AND LEGAL RESPONSIBILITIES FOR:

- **Soil loss as laid out under:**
 - NSW Protection of Environment Act
http://www.austlii.edu.au/au/legis/nsw/consol_act/poteoa1997455/
 - NSW Soil Conservation Act
http://www.austlii.edu.au/au/legis/nsw/consol_act/sca1938215/
 - Water Management Act
http://www.austlii.edu.au/au/legis/nsw/consol_act/wma2000166/
- **Approval or licence requirements to carry out certain types of earthworks.**

Soil erosion is a pollution event for the waterways receiving turbid, nutrient-laden material. Photo: NSW DPI

BMP 2 – MANAGING SOIL STRUCTURE AND COMPACTION

SOIL HEALTH CARD TESTS: GROUND COVER, PENETROMETER, INFILTRATION, STRUCTURE

WHY IS SOIL STRUCTURE IMPORTANT TO ME AS A FARMER?

Good soil structure is one of a farm's greatest assets.

Good Soil Structure

Poor Soil Structure

Photos:
I.Biggs

Soil compaction is a result of compressed structure which means:

- less air, water and root space is available. There are less sites for nutrient storage and there is less area for roots to access so plant nutrition (more fertiliser required) and plant growth are compromised (Refer to the art of bonsai).
- water storage within the soil is lessened as there is less space between the soil structural groups so the total volume that the soil can hold is depleted. The soil dries out sooner and can't hold as much in reserve when recharged.
- drainage rate is impeded in compacted soils so water moulds have longer periods of anaerobic conditions that favour their growth. Root rot limits nutrient and water uptake, so production is less.
- water infiltration rate is much lower so there is less water penetrating into the soil and more run-off, resulting in less effective rainfall. Surface compaction also increases slippage of machinery.

Changes in water-flow pattern due to soil crusting.

Excerpted from *Building Soils for Better Crops*, 2nd Edition, published by the Sustainable Agriculture Research and Education (SARE) outreach office, USDA.

For more information about SARE and sustainable agriculture, see www.sare.org.

Soil compaction reduces pores or spaces in the soil which restricts:

- plant root movement,
- water infiltration and storage,
- air circulation,
- nutrient availability,
- biological activity and
- plant health.

Left: Water ponding under trees.

Photo: B Evans

HOW DO I MANAGE SOIL COMPACTION?

1. MAINTAIN SOIL COVER TO MINIMISE EROSION.

- This is set out in **BMP 1**.

2. MINIMISE IMPACTS OF MACHINERY.

- Limit usage of machinery to essential operations when the soil is moist, as soil structure is more easily compressed at those times.
- Use lighter machinery with turf tyres as this has less compactive effect.
- Plant vigorous ground covers to provide a buffering effect against compaction by machinery.
- Avoid/minimise sweeping or airblasting to move nuts to the edge for harvesting. This removes leaf litter and soil and leaves bare soil and exposed roots.

3. LIMIT HERBICIDE USE.

- Limit the frequency, type and area for herbicide application.
- Ensure that the killed strip doesn't provide a channel for run-off water.

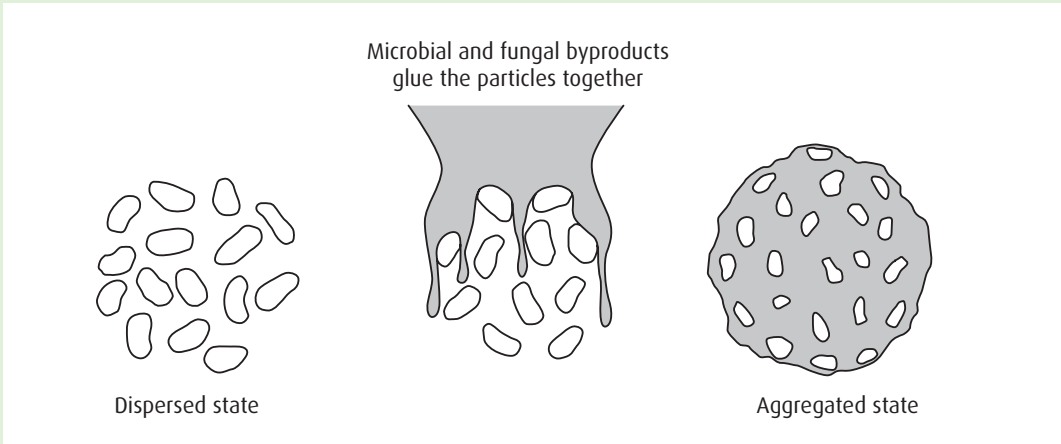

4. REHABILITATE SOIL COMPACTION LAYERS WITH ORGANIC MATTER ADDITIONS AND MECHANICAL TECHNIQUES.

- Plant perennial low growing ground cover that requires minimal mowing.
- Plant appropriate deep rooting species that will help break up the layer.
- Maintain ground cover as it assists in rebuilding soil structure.
- Ripping before an orchard is planted can improve compacted layers as long as it is done at the right moisture content.
- In established orchards careful use of machinery such as ground hog or agriplough can increase aeration. Multiple applications may be required over time to minimise damage to roots.
- Be aware that mechanical techniques to reduce compaction often give only temporary effects. A longer term option may be to instigate management practices that reduce the incidence of compaction.

5. PROMOTE SOIL BIOLOGICAL ACTIVITY.

- This is set out in **BMP 4**.

Soil fauna can have a major influence on soil structure by movement of soil particles during burrowing by larger species, mineralisation and incorporation of organic matter. The influence of soil fauna on the structure of soils may be local, such as within an ant nest or termite mound, or extensive, as by earthworms.

Soil biology provides many eco-services.
Microbial exudates glue soil particles to improve soil structure.
Excerpted from the ATTRA website: <http://attra.ncat.org/attra-pub/soilmgmt.html>

Increasing organic matter levels improves:

- soil structure,
- soil's ability to hold nutrients,
- water infiltration,
- water holding capacity,
- regulates soil temperature,
- biological activity.

The optimum range for crop growth for two different soils.

Excerpted from *Building Soils for Better Crops*, 2nd Edition, published by the Sustainable Agriculture Research and Education (SARE) outreach office, USDA. For more information about SARE and sustainable agriculture, see www.sare.org.

BMP 3 – MANAGING PLANT NUTRITION

SOIL HEALTH CARD TESTS: GROUND COVER, DIVERSITY OF SOIL LIFE, ROOT DEVELOPMENT, SOIL PH, LEAF COLOUR

WHY IS SOIL MANAGEMENT IMPORTANT TO PLANT NUTRITION?

Fruit and nut trees need a consistent supply of nutrients to maintain plant health and good production.

- High organic matter levels are necessary to maintain and increase nutrient storage and availability for general soil health and consequently for fruit and nut production.
- Dieback from nutritional stress lowers energy availability for the tree. Yield falls proportionally to the level of stress.
- The ability of the roots to access nutrients is limited by topsoil depth, structure, soil moisture content, humus levels, biological activity, nutrient tie-up, nutrient presence and additions.

Left: Compost provides organic matter and nutrition. Photo: D Roby

HOW DO I MANAGE SOIL FOR PLANT NUTRITION?

1. DETERMINE SOIL AND PLANT NUTRITION REQUIREMENTS.

- Using the soil sampling guide (see Appendix 5), provide soil samples to a recognized soil laboratory for analysis.
- Conduct the Soil Health Card (SHC) tests.
- Prepare a soil and plant nutrition plan based on laboratory analysis and Soil Health Card results.

2. INCREASE AND MAINTAIN HIGH LEVELS OF ORGANIC MATTER TO ENSURE MAXIMUM NUTRIENT CYCLING BY:

- increasing biological activity and biodiversity,
- increasing organic carbon levels,
- improving nutrient holding and exchange,
- improving root health due to better soil structure,
- improving water infiltration, holding and drainage,
- 'unlocking' phosphorus.

3. MANAGE SOIL PH

A number of long-term chemical factors operate in bare soil strips in orchards. A major problem is soils becoming more acid. In one local orchard, pH dropped from 6.3 to 4.3 in 4 years and eventually declined to 4.0 as a result of leaching and the acidifying effect of ammonium sulfate nitrogen fertiliser.

- Ameliorate low soil pH to improve activity of soil organisms. A high level of biological activity maintains minerals in the nutrient cycle; fungal hyphae are major stores of calcium. Good microbial activity ensures release of nitrogen and sulphur from organic matter.
- Maintain humus or soil organic carbon levels to buffer against fluctuation in pH and reduce aluminium toxicity.
- Supply calcium.
- Use appropriate forms of fertilisers to reduce acidification.
- Use with caution and in small amounts if using highly soluble acidic or salty fertilisers. They supply high levels of nutrient but can affect soil chemistry and biology negatively. This can lessen soil health by lowering existing biological biodiversity limiting the availability of nutrients in the soil.

At pH below 5.0 there may be:

- | | |
|---|--------------------------------------|
| · reduced microbial activity affecting release of nitrogen and sulphur from organic matter, | deficiencies of the elements: |
| · high phosphorus fixation, | · calcium |
| · reduced nodulation of legumes. | · magnesium |
| | · molybdenum |
| | · boron |
| | toxicities of: |
| | · aluminium |
| | · manganese in solution |

4. APPLY FERTILISERS AND SOIL AMENDMENTS APPROPRIATELY.

- Apply fertilisers at appropriate times and under conditions that facilitate uptake without leaching. Leaching nutrient contaminates the water cycle and causes off farm problems.
- Maintain fertility by replacing nutrients removed by harvest, leaching and nutrient fixation.
- Protect the roots and soil from strong nutrient solutions. Root hairs can be killed by strong nutrient solutions and if leached they can leave the soil more acidic by combining with alkaline elements including Ca, Mg and K.
- Apply minerals such as calcium additions to improve soil structure by increasing grouping of clay particles. This also improves the soil pH for soil organisms increasing capacity for worm activity, whose tunnelling improves soil structure.
- Ensure phosphorus is available as it is an important mineral for soil organism energy metabolism.
- As part of a macadamia nutrition program, bulk or pelleted poultry manure and compost provide organic matter as well as nutrients. Encouraging vigorous ground cover inter-row provides on site mulch and nutrient cycling as well as protecting soil structure and minimising erosion.

5. BE AWARE OF SOIL MOISTURE CONTENT AND OPTIMUM WATER RANGE.

- Improve the water holding capacity of the soil with additions of organic matter carbon.
- Supplementary irrigation maintains soil biological activity and nutrient uptake into roots, minimising nutritional stress.
- Apply fertiliser under soil moisture and climatic conditions that facilitate uptake without leaching.
 - When heavy rain events are likely use slow release options because soluble fertilisers will leach.
 - In dry conditions use fertigation.
 - Avoid risk of leaching and promote efficient use of fertilisers with incremental applications, i.e. supply smaller amounts more often.

BMP 4 – MANAGING SOIL BIOLOGY

SOIL HEALTH CARD TESTS: GROUND COVER, SOIL STRUCTURE, DIVERSITY OF SOIL LIFE, ROOT DEVELOPMENT, EARTHWORMS, SOIL PH, BIO-TURBATION, CALICO STRIP TEST.

WHY IS SOIL BIOLOGY IMPORTANT TO ME AS A FARMER?

Soil organisms manage nutrients, determine soil characteristics and protect plants.

A diverse biological community sustains:

- decomposition of organic matter,
- nutrient cycling:
 - mineralization,
 - nutrient storage,
 - nutrient release,
- soil structure,
- root health,
- soil's ability to hold moisture,
- degradation of harmful chemicals,
- disease suppression.

In a healthy soil, soil organisms can represent 3% of the dry matter in your soil. A single teaspoon can contain tens of thousands of different species of organisms. They include bacteria, fungi, mites, ants, millipedes, beetles, earthworms, slugs and snails. Almost all of these are beneficial organisms and they actively manage or out-compete soil borne diseases/pests.

Excerpted from Soil Biology Primer [online].
 Available: soils.usda.gov/sqi/concepts/soil_biology/biology.html [Feb 2008].

Soil organisms derive their energy and nutrients from breaking down plant and animal material. When digesting this material they release oxygen and mineral nutrients that plants can use. When the soil organisms die they decompose and release more nutrients, so are valuable contributors to soil fertility.

Soil fauna can also have a major influence on soil structure by movement of soil particles during burrowing by larger species, mineralisation and incorporation of organic matter. Many soils under rainforest and wet sclerophyll forest in Tasmania, for example, have been found to consist entirely of earthworm casts and burrows. (Laffan, Kingston 1997)

HOW DO I MANAGE SOIL BIOLOGY?

1. ENSURE SOIL IS PROTECTED BY GROUND COVERS.

- Ground covers preserve soil moisture.
- Ground covers regulate soil temperature to suitable range for organisms.
- Living ground covers trap carbon on site through photosynthesis and supply nutrients and energy from root systems and vegetative growth to soil organisms. i.e. soil bacteria fix nitrogen and so add it to the soil.

- Low organic matter (OM), soil compaction and high acidity in orchards contribute to low levels of biological activity.
- Biological activity moves organic matter down the soil profile.

Left: Note lack of OM movement down the soil profile.

Photo: I.Biggs,

2. BUILD UP AND MAINTAIN ORGANIC MATTER (OM) CONTENT.

- Vary the OM content. Composts, manures and mulches as well as on site or inter-row material can significantly improve soil biological populations.
- Organic matter inputs can be increased through:
 - incorporating organic fertilisers into plant nutrition programs,
 - minimising herbicide use,
 - low light tolerant ground covers,
 - maximising vigorous inter-row growth.

Soil animals need certain soil conditions to grow and survive.

Healthy and diverse soil biological communities require:

- food from organic matter for energy,
- root exudates,
- oxygen-aerated soil structure,
- adequate minerals,
- adequate moisture,
- warmth (but not extreme heat),
- near-neutral soil pH.

3. REDUCE HARMFUL CHEMICAL USE, I.E. HERBICIDES AND PESTICIDES.

- Raised copper levels inhibit earthworm activity.
- High concentrations of nitrogen and chlorine in fertiliser inhibit fungi and other soil organisms.

4. SUPPORT MICROBIAL ACTIVITY.

- Maintain leaf growth to deliver energy to soil biology.
- Use supplementary irrigation, if available when soil is dry, to maintain the benefits of soil biological activity.
- Supply adequate inputs of calcium and phosphorus.
 - Calcium improves clay structure, pH, cation exchange capacity (CEC) and bacterial activity supporting a food chain which releases high levels of nutrients. Calcium is stored and released by fungal hyphae maximising retention in soil and availability to plant roots.
- Phosphorus is the mineral basis of all energy storage and use in plant and animal cells.

Appendix 1

CONSIDERATIONS FOR SOIL HEALTH WHEN ESTABLISHING A NEW ORCHARD

Productive fruit and nut trees require healthy soils with:

- strong structure,
- free drainage,
- a high cation exchange capacity (CEC),
- high organic matter levels and
- high soil biological activity.

Site selection

The applicable Soil Health Card tests for the above will help rate suitability. Some specific issues to consider are:

- Topsoil depth can be assessed by a number of excavations to a minimum topsoil depth of 1.5m.
- Red clay loams typically have deeper topsoil and better structure than chocolate clay loams or loamy clay.
- Sandy soils have low water and nutrient holding capacity.
- Soil type cannot be changed but topsoil depth can be slightly modified by mounding before planting. This allows movement of excess water away from the tree row to a grassed inter-row with a fall designed to take it to natural drainage.
- Internal drainage, root area, nutrient availability, biological activity and nutrient balance can all be modified but on a less suitable soil type more inputs are needed to support the same level of yield. Environmental variations such as drought or persistent high rainfall pose increased risks to soil and plant health.
- Previous history of the site with reference to soil erosion or compaction, nutrient status and supplementary water availability will help rate suitability.
- Problems with water infiltration, holding capacity and drainage, root area available, nutrient availability, and soil pathogen risk can be related to soil type and previous history of use.
- Assess and test the soil for fertility, physical and biological condition using Soil Health Card tests and standard agronomic soil tests.
- Identify areas and aspects of the farm where soil conditions need to be improved or rehabilitated such as compacted soils and gully erosion.
- Prepare a soil management plan.
- Avoid planting trees in drainage lines.
- Mound tree rows, leaving a shallow broad based grassed inter-row for drainage.
- Avoid planting on steep slopes. Do not plant on slopes > 15 degrees or 20%.
- Establish grassed waterways and shallow grassed drains above and within the orchard.
- Establish appropriate drains to handle run-on.
- Establish rows in a north south orientation, which allows light on both sides of tree.

- When selecting row spacing, consider:
 - aspect
 - life stages of the orchard so as to ensure light penetration even at canopy closure,
 - 10mx5m row spacing for long term management of the orchard for soil health,
 - how you will maintain 100% living ground cover in drainage lines,
 - how you will maintain 90-100% mulch/living ground cover in the tree line & how you will ensure any bare soil is covered by mulch and or vegetative ground cover.

Appendix 2

BMP 2 SOIL COMPACTION – ADDITIONAL INFORMATION

A lump of soil when broken in the hand, generally results in natural aggregates or 'peds'. The size and shape of the peds are the aspects of the soil structure.

Soil structure is the way the soil particles, sand, silt, clay and organic matter are arranged and the size and shape of gaps and channels (or pores) between them. The pores provide the space for air, water, roots, soil fauna and flora.

Exposed plateau landscape soils on perennial horticulture orchards are affected by:

- run-off that causes sheet and gully erosion,
- concentrated stem flow (water running down the trunk during heavy rain) which erodes soil,
- impact of raindrops and large water droplets falling through the canopy that can shatter soil peds and dislodge soil particles,
- loss of organic matter,
- compaction by machinery and use of other equipment such as blowers, etc.

Compaction, erosion, and declining organic matter levels all degrade soil structure, which results in:

- reduced rain fall infiltration resulting in increased run-off and erosion,
- reduced soil porosity, aeration and water storage.
- poor drainage and reduced trafficability,
- reduced root growth,
- declining yields,
- creation of a hostile soil environment for soil organisms.

Appendix 3

BMP 3 – SOIL HEALTH FOR PLANT NUTRITION – ADDITIONAL INFORMATION

The Alstonville Plateau Landscape soils are generally low in nutrients, have a low cation exchange capacity (low ability to hold nutrients) and low pH with a number of associated mineral toxicities and deficiencies. Also organic matter levels have declined to low levels where land has been cleared.

Fruit and nut production relies on good levels of soil organic matter, pH, cation exchange capacity (ability to hold nutrients), calcium and available phosphorus. High organic matter levels are necessary to maintain and increase nutrient storage and availability for general soil health and crop production.

Phosphorous (P) availability is reduced in krasnozem/ferrosol soils due to the high free iron content of the soil. Acid phosphates such as super phosphate are locked up very quickly by the soil with only a 5 – 10 % recovery.

The form of P available from compost and animal manures is in an organic form. Slow release of these manures is less prone to being locked up by the soil. Also release by soil biological process maintains nutrient availability.

Soil tests and plant diagnostic techniques (leaf testing) are the best way to match fertiliser requirements. Not enough fertiliser means nutrient deficiency. Too much fertiliser can also reduce yields, and more importantly pose serious environmental risks and waste money.

Ensure nutrient cycling is maximised by increased organic matter content and increase in beneficial biological activity.

Trials using composted macadamia husk and chicken litter have shown improvements in microbial activity and water holding capacity in degraded macadamia and avocado soils. Nutrient availability and fertiliser use efficiency is increased as organic carbon levels rise in the soil.

Use ground cover, mulch and compost to increase the organic matter content of the soil and create a soil environment that is supportive of soil organisms.

Appendix 4

BMP 4 SOIL BIOLOGY – ADDITIONAL INFORMATION

Agriculture production activities generally make soils less healthy and therefore less conducive for soil organisms. These activities decrease the diversity of soil animals (number of species) and soil community structure.

Agricultural practices change soil conditions, making it harsher for some soil organisms.

Changes include the following;

- Soil moisture is decreased.
- Diminished ability of soil biology to protect plants.
- Soil temperatures rise with greater fluctuations.
- Less organic matter is in the soil and often only from one or two plants rather than a range.
- Soil pH becomes more acidic.
- Soil is often disturbed by erosion, vehicle traffic and tillage which removes organic matter (Above information sourced from www.soilhealth.segs.uwa.edu.au)

In macadamia orchards, studies (**Healthy Soils in Macadamia Orchards**, Van Zwieten, see page 29) have demonstrated there have been significant declines in soil carbon content and increase in soil bulk density with decreases also in microbial activity, earthworm numbers and soil biomass in general. The same studies also showed that macadamia orchards have fewer earthworms than control plots and other subtropical production systems sampled.

Trials using composted macadamia husk and chicken litter showed improvements in microbial activity and water holding capacity in degraded macadamia soils (Van Zwieten et al).

A survey of macadamia roots in a local mulch trial also found a good association between healthy trees, increased fibrous roots and mulch. This was found to be the most effective treatment in ameliorating macadamia dieback.

Appendix 5

HOW TO TAKE A SOIL SAMPLE FOR LAB ANALYSIS

NSW DPI guide to collecting soil samples for lab testing.

Checklist:

- Plan your soil testing with your local District Agronomist, Horticulturist or advisor.
- Collect samples with clean equipment.
- Send samples to the laboratory as soon as possible after collection.

Tools required for sampling:

- Soil corer or spade
- Buckets
- New plastic bag or sample container (located in soil kit)
- Labels if more than one sample is collected
- Record sheet to record sample site and sample.

Remember a soil test is only as good as the care taken in sampling. Tools and equipment should be clean prior to sampling.

Taking a soil sample

- Look at the soils in the area you intend to sample. Submit a separate soil sample from each soil type (e.g. clay, loam or sand) and from paddocks that have been managed differently, because these factors affect fertiliser needs.
- For each sample, thoroughly mix a minimum of 20 soil cores (see following paragraph) in one bucket (the more cores taken the more reliable the sample). Fill the container supplied in the kit with the sample from the bucket. If you have collected multiple samples you can submit your samples in 500 gram bags to the laboratory. Make sure samples are clearly labelled.
- Soil cores should be collected at 0–10 cm depth. Avoid collecting the surface material such as leaf or organic matter. Deeper cores may need to be taken for the investigation of subsurface acidity and salinity or for larger horticultural crops (please contact your advisor for this advice).
- Once the samples have been collected they should be sent as soon as possible to the laboratory for analysis.

A map and written plan of the soil sampling area is essential for interpreting results and any subsequent testing. It is recommended that soil cores be collected along a fixed transect (e.g. 1 and 2). This method allows for re-testing and better monitoring of changes in fertility than random sampling. In areas where tree crops are planted samples should be collected along rows.

To obtain representative samples, do not sample from unusual sites such as: stock camps, manure patches, gateways, dams or water troughs, feedout areas, old fertiliser stockpiles, paddocks that have had fertiliser applied in the last 3 months.

Appendix 6

AN EXAMPLE: BIOLOGICAL FARMING NUTRITION MANAGEMENT PRACTICES FOR ORCHARDS

- Use mineral fertiliser such as a slow release lime and rock phosphate on an annual basis. Application at any time as long as there is a degree of soil moisture for biological activity to make the fertiliser available.
- Apply compost and / or chicken litter two (2) times per year to coincide with growth flush and moist times of the year.
- At flowering use foliar fish emulsion, which has nitrogen and a range of trace elements, which helps fruit/nut set.
- Use of foliar nitrogen increases nut retention – the nuts stay on the tree longer.
- Use small amounts of Potassium (K) sulfate on a more regular basis to top up K levels in October, December and February.
- Use groundcovers for plant nutrition.

This type of regime:

- minimizes leaching,
- provides a slow and steady release over the year,
- adds organic matter,
- supports soil biology,
- supplies nutrients to trees,
- improves soil structure.
